| ai-request                                                             | 200  | 200      |
| parallel-ai                                                            | 200  | 200      |
| mitch-master                                                           | 200  | 200      |
| mitch-master                                                           | 200  | 200      |
| daily-operations · failure scenario                                    | 500  | 500      |
| 10 saved scenarios · all observed HTTP statuses match expected values  |      |          |
| Model endpoints and database sink substituted · no live-provider claim |      |          |

## Problem

Hospitality teams repeat daily operations, menu, content and feedback tasks. I used my operating experience to model these as inspectable workflows with explicit inputs and responses.

## Engineering decision

A TypeScript/Node.js platform connects eight n8n workflows. Synthetic HTTP scenarios check request handling, provider failure and parallel-branch merging before connecting external systems.

## My contribution

Founder and engineer: hospitality requirements, backend implementation, workflow integration and test documentation.

## Visual evidence

Visual summary of saved synthetic execution responses from 13 September 2026. Expected HTTP 500 checks a failure path; model endpoints and database sink are substituted.

# Engineering evidence

Dated verification, implementation scope and remaining work

## Implementation

The backend uses Node.js, TypeScript and Express; the frontend uses Next.js/React with PostgreSQL persistence. Supporting services include Redis and Qdrant. Provider routing includes configurable cloud providers and local Ollama/LM Studio integrations.

The n8n master routes to menu, social, strategy, feedback and operations workflows. The combo route currently returns a plan without executing its steps.

## Dated execution evidence

The 13 September verification recorded 193 passing backend tests with none skipped. Eight n8n workflows were exercised through ten synthetic HTTP scenarios, including provider failure and parallel-branch merging.

Page 1 copies route names and observed/expected HTTP statuses from saved responses. All ten match their expected status, including the deliberate 500. Model endpoints and database persistence were substituted. This figure is not a new run or evidence of live model quality or database durability.

## Status and evidence access

Offline portfolio prototype. This reviewed case study is the application evidence link; the repository is not linked here while public-history cleanup remains pending. That history finding is unresolved by this document update.

A historical GitHub Actions run on 12 February 2026 built an image and updated AWS ECS. Published Terraform modules are separate implementation evidence, not proof that they provisioned that run. No current service health, SLA, customer usage or independently assessed compliance is claimed.

## Next validation

Validate real-provider behaviour and database persistence, resolve the public-history findings and complete security/privacy review before external use. Human approval remains the intended boundary for external posts, messages, filings and purchases.
